# Scaling of fixed-dose combinations in children 

Massimo Cella, Frank L. Kloprogge, Meindert Danhof, Oscar Della Pasqua

## Introduction

Drug combinations with a fixed dose ratio are standard therapy for various infectious diseases. In these cases, dose adjustment is often based on the assumption that the effect of developmental growth on pharmacokinetics, pharmacodynamics and risk : benefit ratio for each agent is comparable across populations. Such an assumption may however be inappropriate for many drugs.

Here we demonstrate the relevance of a model-based approach for the purposes of pharmacokinetic bridging and selection of paediatric doses for drug combinations. The antimalarial drugs atovaquone (ATV) and proguanil (PGN), which are prescribed in the ratio 2.5:1 in adults and children, are used as paradigm compounds.

## Methods

In a bridging study, dose adjustments are aimed at target exposure equivalent to that observed in a reference population. In this investigation the predicted median exposure (AUC) in adults was obtained from a population PK model for ATV and PGN. The parameter estimates from the PK model were then used to simulate drug exposure in children following different dose levels. Dose selection was based on a threshold value for AUC in at least $80 \%$ of the paediatric population. Simulation datasets included patients across a wide range of weights ( $5,10,15,25,35,70 \mathrm{~kg}$ ).

Nine clinical trials from GlaxoSmithKline's clinical database were used for pharmacokinetic modelling. Different doses and dosing regimens were available for ATV ( 62.5 to 1000 mg ) and PGN ( 25 to 400 mg ).

|  | atovaquone |  | proguanil |  |
| :--- | :---: | :---: | :---: | :---: |
|  | CHILDREN <br> (mean / range) | ADULTS <br> (mean / range) | CHILDREN <br> (mean / range) | ADULTS <br> (mean / range) |
| Africans | 423 | 106 | 402 | 105 |
| Orientals | 59 | 195 | 46 | 174 |
| Body weight (Kg) | $26.5(5.4-68)$ | $55.6(39-110)$ | $26.8(5.4-68)$ | $62.5(39-110)$ |
| Age (years) | $8.8(0.3-17)$ | $29.2(18-65)$ | $9.0(0.3-17)$ | $40.5(18-79)$ |
| Sex (m/f) | $247 / 234$ | $268 / 33$ | $225 / 222$ | $207 / 72$ |
| Blood samples | $2.2(1-13)$ | $5.1(1-15)$ | $1.9(1-13)$ | $6(1-19)$ |
| per subject | 2.2 |  |  |  |

## Pharmacokinetics of atovaquone

A one-compartment model with 1st order absorption and 1st order elimination was used to describe the PK of atovaquone. Body weight and ethnicity (Africans or Orientals) were covariates on clearance (CL). The effect of BW on CL was characterised by an exponential model:

$$
C L=C L_{\text {RACE }} *(B W / 70) \operatorname{EXP}
$$

BW was also linearly correlated with volume of distribution $(\mathrm{V})$.

PK modelling - Diagnostics and parameter estimates for atovaquone.

## Pharmacokinetics of proguanil

The PK of PGN was also described by a one-compartment model with 1st order absorption and 1st order elimination.

The correlation between BW on CL was similar to the one used for ATV, whilst the effect of BW on V was expressed in the following equation:

$$
\mathrm{V}=\mathrm{INT} \mathrm{AGE}_{\mathrm{AGE}}+\mathrm{SLOPE}_{\mathrm{AGE}} * \mathrm{BW}
$$

Where $I N T_{\text {AGE }}$ and SLOPE $_{\text {AGE }}$ indicate respectively a different intercept and slope for adults and children.

| Fixed effects | Estimate |
| :---: | :---: |
| CL, Africans (L/h) | 81.9 |
| CL, Orientals (L/h) | 44.4 |
| Exp on CL | 0.548 |
| V inter, adults (L) | 1530 |
| $\checkmark$ inter, children (L) | 686 |
| $V$ slope, adults (L/Kg) | 11.7 |
| V slope, children (L/Kg) | 10.9 |
| KA (1/h) | 0.912 |
| IN |  |
| CL | 23.7 \% |
| $\checkmark$ | 67.1 \% |
| KA | 167.6 \% |
| Residual variability |  |
| Proportional error | 25.6 \% |
| Additive error ( $\mu \mathrm{g} / \mathrm{L}$ ) | 5 |

- Our analysis shows how differences in exposure ratios can be estimated when scaling fixed-dose ratios from adults to children. Whilst data on efficacy and safety support the use of a fixed dose-ratio for ATV and PGN, this is not generalisable to all drugs.
- The effect of covariates on drug disposition cannot be assumed constant for different compounds, age and ethnic groups.
- Appropriate bridging and dose selection for drug combinations in children should therefore be based on exposure ratios rather than dose ratios.
